Motivation

What is an F-test, what is wrong with it and how can we improve it?

Preliminaries - The Multitaper Method(MTM)

• It is the primary tool for spectral estimation that balances the variance and bias of the estimated spectrum.

$$\overline{S}(f) = \frac{1}{K} \sum_{k=0}^{K-1} |Y_k(f)|^2,$$
(1)

$$Y_k(f) = \sum_{t=0}^{N-1} v_t^{(k)} e^{-2i\pi f t} x_t,$$
(2)

where Y_k are the eigenspectra and $v_t^{(k)}$ are the Slepian sequences in the time domain.

• The Slepian sequences are defined for a choice of *NW*, with the parameters of *NW* and *K* being user selected.

Preliminaries - F-test for line components

• Using the eigenspectra that are found when performing the MTM, we can think of the *F*-test as essentially complex valued linear regression,

$$Y_k(f) = \mu(f)V_k(0) + \epsilon(f), \qquad (3)$$

$$V_k(f) = \sum_{t=0}^{N-1} v_t^{(k)} e^{-2i\pi ft},$$
(4)

where we assume $\epsilon(f) \sim CN(0, \sigma_{noise}^2)$.

• After performing this regression, we are interested in testing the null hypothesis, $H_0: \mu(f) = 0$.

Preliminaries - F-statistic calculation

• To test H_0 , we calculate the *F*-statistic which is defined to be:

$$F(f) = (K-1) \frac{|\hat{\mu}(f)|^2 \sum_{k=0}^{K-1} |V_k(0)|^2}{\sum_{k=0}^{K-1} |\hat{r}_k(f)|^2},$$
(5)

$$\hat{r}_k(f) = Y_k(f) - \hat{\mu}(f)V_k(0),$$
 (6)

$$\hat{\mu}(f) = \frac{\sum_{k=0}^{K-1} V_k(0) Y_k(f)}{\sum_{k=0}^{K-1} |V_k(0)|^2}.$$
(7)

イロト イポト イヨト イヨト

The F-statistic should follow an F(2, 2K - 2, α) distribution if H₀ is true.

Preliminaries - Examples

Problems With The F-Test

The test suffers lowered detection rates and higher rates of false detection when:

- There is a low signal to noise ratio.
- The choice of parameters NW and K are made incorrectly.
- The data is non-stationary.

Residual effect on F-Test

• After examining the residuals from the *F*-test, we noticed that the values were close to zero for some falsely detected signals and the values were quite large for actual signals.

Effect of Residual values on the F-Statistic

Bootstrapping residuals F-test - motivation

- Ideally, if all the structure in the residuals were removed (we have chosen *NW* and *K* correctly), they should be random variables that are independent of frequency.
- Treating them as independent realizations, we can perform a bootstrap to get a better estimate of the distribution of our *F*-statistic.
- We do so by re-sampling the residuals with replacement and computing a new *F*-value. We then take the mean of a number of re-sampled *F*-values to get an unbiased estimate of the location of our test statistic.

- 4 目 ト - 4 日 ト - 4 日 ト

Bootstrapped F-Test Algorithm

- The Bootstrapped residuals F-test algorithm is as follows,
 - Compute the F-test.
 - 2 Re-sample the residuals.
 - **3** Compute new values for $\hat{Y}_{k}^{(1)}(f)$, $\hat{\mu}^{(1)}(f)$, $\hat{r}_{k}^{(1)\prime}(f)$, and $\hat{F}^{(1)}(f)$.
 - Repeat steps 2 and 3 M times (M > 100) and take the mean of F-statistics found for each re-sampling.
 - Lastly to test for signal detection we check if this value exceeds an empirical cut-off to determined by the noise level of the time series and parameter choices..

Bootstrapped F-Test Example Atrial ECG

Bootstrapped F-Test - Simulations

- We wanted to compare the ability of the Bootstrapped *F*-test to identify a single sinusoid with varying levels of amplitude within Gaussian noise of constant variance to that of the *F*-test.
- We simulated a data set, $Y_t = \alpha \sin(2\pi(.125t)) + z_t$, with $z_t \sim N(0, 1)$, the amplitude of the signal, α varied across (0, .5].
- We used N = 1000, NW = 4, and K = 7 for both tests.

イロト 不得下 イヨト イヨト

Test comparison results

• The result of the tests was that the re-sampled *F*-test had higher detection rates for signals of low to moderate power and performed equally well otherwise.
